

1,5 A, Step –Up/Down/Inverting Switching Regulator

DESCRIPTION

MC34063 is a monolithic control circuit containing the primary functions required for DC-to-DC converters. These devices consist of an internal temperature compensated reference, comparator, controlled duty cycle oscillator with an active current limit circuit, driver and high current output switch. This series was specifically designed to be incorporated in Step-Down and Step-Up and Voltage-Inverting applications with a minimum number of external components.

FEATURES

- Operation from 3.0 V to 40 V Input
- Low Standby Current
- Current Limiting
- Output Switch Current to 1.5 A
- Output Voltage Adjustable
- Frequency Operation to 100 kHz
- Precision 2% Reference
- 8 pin DIP and SO package

The circuit diagram shows a precision current source. An input voltage V_{in} (4.5 V to 6.0 V) is applied to pin 6 through a resistor R_{sc} (0.24 Ω) and a 100 μF capacitor. Pin 8 is connected to V_{in} . Pin 1 is connected to ground. Pin 2 is connected to a load inductor L (88 μH) and a 1500 pF capacitor. Pin 3 is connected to a 1.25 V reference voltage divider (pins 4 and 5) and a 1000 μF capacitor. Pin 4 is connected to the non-inverting input of an op-amp (pin 5) and a 1.25 V reference voltage divider. Pin 5 is connected to the inverting input of the op-amp. The op-amp output (pin 7) is connected to the base of a PNP transistor $Q1$. The emitter of $Q1$ is connected to ground. The collector of $Q1$ is connected to the base of an NPN transistor $Q2$. The emitter of $Q2$ is connected to ground. The collector of $Q2$ is connected to the load inductor L . A 1N5819 diode is connected in series with the load inductor. The output voltage V_{out} is measured across the diode. The output current is $-12 V/100 mA$. An optional filter is shown at the output, consisting of a 1.0 μH inductor and a 100 μF capacitor.

V_{sat} = Saturation voltage of the output switch.

V_F = Forward voltage drop of the output rectifier.

The following power supply characteristics must be chosen:

V_{in} - Nominal input voltage.

V_{out} - Desired output voltage,

$$|V_{out}| = 1.25 \left\| 1 + \frac{R_2}{R_1} \right\|$$

I_{out} - Desired output current.

f_{min} - Minimum desired output switching frequency at the selected values of V_{in} and I_O .

$V_{ripple(p-p)}$ – Desired peak-to-peak output ripple voltage. In practice, the calculated capacitor value will need to be increased due to its equivalent series resistance and board layout. The ripple voltage should be kept to a low value since it will directly affect the line and load regulation.
